3.12 **MPE** calculation

These equations are generally accurate in the far field of an antenna but will over predict power density in the near field, where they could be used for making a "worst case" prediction.

 $S = PG/4\pi R^2$

where S = power density (in appropriate units, e.g. mW/cm²)

P = power input to the antenna (in appropriate units e.g. mW)

G = power gain of the antenna in the direction of interest relative to the isotropic radiator

R = distance to the center of radiation of the antenna (appropriate units e.g. cm)

Or

 $S = EIRP/4\pi R^2$

where EIRP = equivalent isotropically radiated power

Calculation:

(Calculated for max. EIRP)

EIRP: 34.8 dBm = 3020 mW

calculated at distance of 20 cm:

 $= 3548.1 / 4\pi 20^2 = 0.60 \text{ mW/cm}^2$ power density

Limit:

1mW/cm² is the reference level for general public exposure according to the OET Bulletin 65, Edition 97-01 Table 1.
